The 8 stages of AI development practice

1

Zero or near-zero AI

2

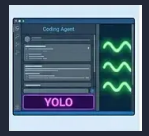

IDE assistant with permissions

3

IDE agent in YOLO mode

4

Wide agent inside the IDE

5

Single CLI coding agent

6

Multi-agent CLI workflow

7

10+ agents, hand-managed

8

Building an orchestrator

PRACTICE SHIFT

The shift is from asking an assistant to operating a delivery system.

- Early stages improve individual flow.
- Middle stages increase throughput with CLI agents.
- Late stages create a coordination problem.
- Gas Town appears when hand-management stops scaling.

TAKEAWAY
AI development evolves from individual assistance to organizational coordination.

FROM PRACTICE TO ORGANIZATION

Steve Yegge frames the shift from individual AI coding to AI-native software delivery.

Vibe Coding
Production-grade software with AI coding agents.

Gas Town
An operating model for coordinating many agents around real repositories.

Beads
A Git-backed work ledger for agentic engineering workflows.

Cover source: IT Revolution / Simon & Schuster

Gas Town: a town-shaped delivery system

TOWN

Agent headquarters

A separate operating space where orchestration, identity, mail, and work tracking live.

MAYOR

Chief of staff

The front door: absorbs worker noise and turns intent into coordinated work.

RIGS

Project factories

Polecats, Crew, Witness and Refinery operate around real repositories.

TOWN AS OPERATING MODEL

Gas Town makes vibe coding operational without pretending the chaos disappears.

- Many coding agents become first-class workers with visible identities.
- Beads provide the Git-backed ledger for work, memory, mail, and provenance.
- Convoys track delivery streams; Polecats execute the work.
- Witness and Refinery keep the system from turning into merge chaos.

TAKEAWAY

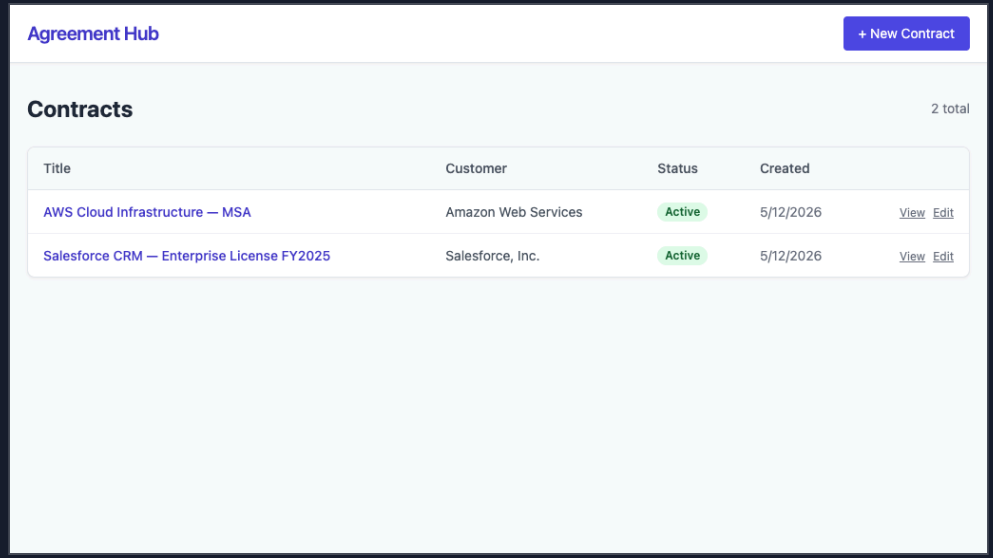

Gas Town turns agentic coding into observable, coordinated software delivery.

Demo application

AGREEMENT HUB

A CRUD Contract Lifecycle Management application used as a realistic delivery target.

- Stack: React/Vite frontend, Express/TypeScript backend, SQLite database.
- Gas Town works on a forked repository, so the demo starts from a clean baseline.
- The demo is real: the outcome may differ from the initial plan.

DEMO FLOW

Start the demo loop: open Agreement Hub → show current state → ask the Mayor.

From here, each Live Signal marks what to observe next.

Why single-agent workflows break

SINGLE AGENT

Great local assistant

One context, one thread of execution, one working branch.

01

Context saturation

Important constraints disappear as the session grows.

02

Sequential execution

Throughput is bounded by one worker loop.

03

No coordination layer

Dependencies and ownership stay implicit.

04

Merge pressure

Parallel changes become hard to integrate safely.

05

No operational supervision

Stuck work is difficult to observe and recover.

PROBLEM

AI coding works locally, but software delivery is organizational.

- Context windows do not model dependencies.
- Sequential work limits throughput.
- Parallel work creates integration pressure.
- Supervision becomes a first-class concern.

TAKEAWAY

Software delivery is organizational. The bottleneck becomes coordination.

Gas Town organizes work, not prompts

INPUT

Human intent

Natural language request, incomplete by design.

ORGANIZATION LAYER

Gas Town structures delivery

- **Mayor** plans and coordinates.
- **Beads** make work addressable.
- **Convoys** track delivery streams.
- **Witness & Refinery** keep execution observable.
- **Polecats** do the work.

OUTPUT

Observable delivery

Status, dependencies, ownership, progress, and merge flow become inspectable.

RESPONSE

Gas Town turns intent into shared delivery objects.

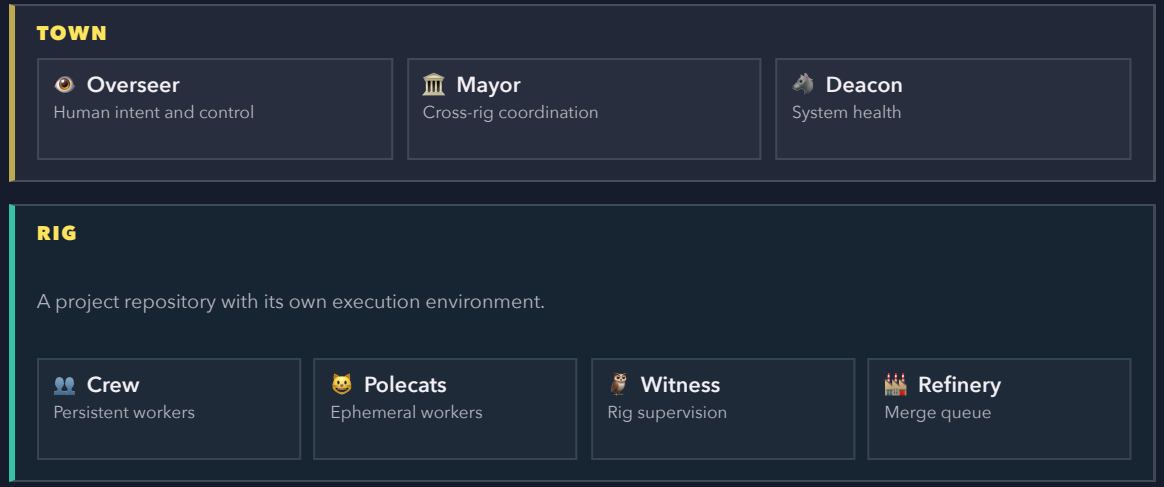

- Mayor separates planning from execution.
- Beads and convoys make work addressable and trackable.
- Witness and Refinery make supervision and convergence visible.
- Polecats execute the work.

TAKEAWAY

Scale comes from shared coordination, not bigger prompts.

LIVE SIGNAL The Mayor turns a high-level request into beads, convoys, assignments, and visible status.

The Organization

WHY IT MATTERS

Gas Town is organized around a town and one or more rigs.

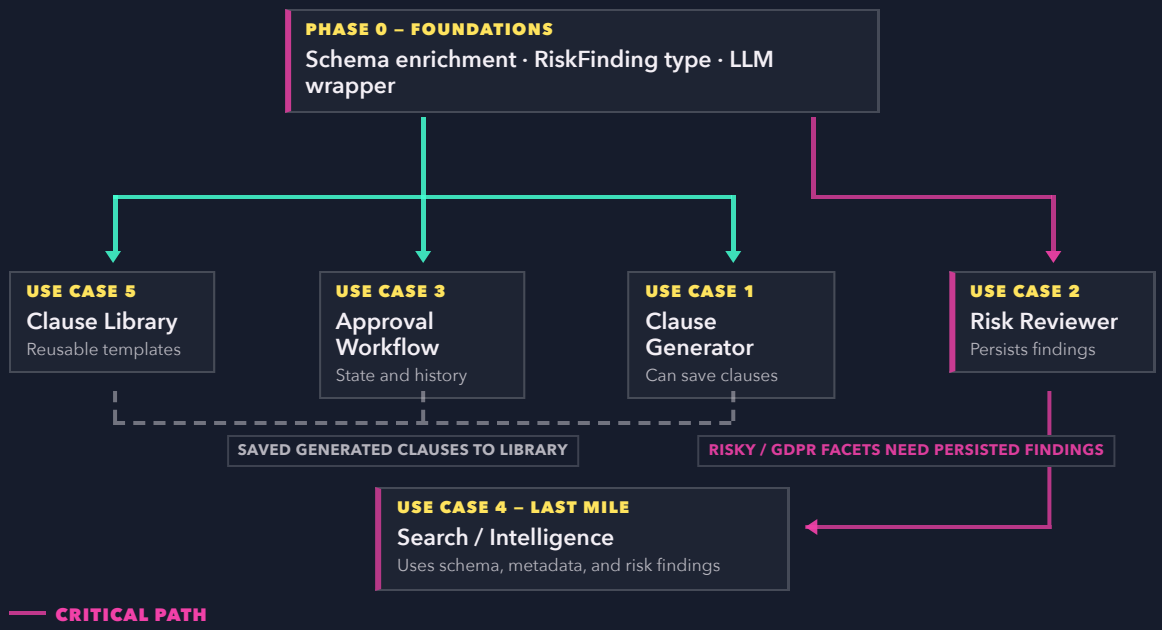

- The Town coordinates across repositories.
- Each Rig is attached to a real codebase.
- Crew members are persistent; Polecats are disposable execution workers.
- Witness and Refinery are rig-level operating roles.

TAKEAWAY

Gas Town separates coordination, execution, supervision, and integration.

LIVE SIGNAL Identify the rig, the persistent crew, and the disposable workers attached to the repository.

Beads: work breakdown & dependencies

WHY IT MATTERS

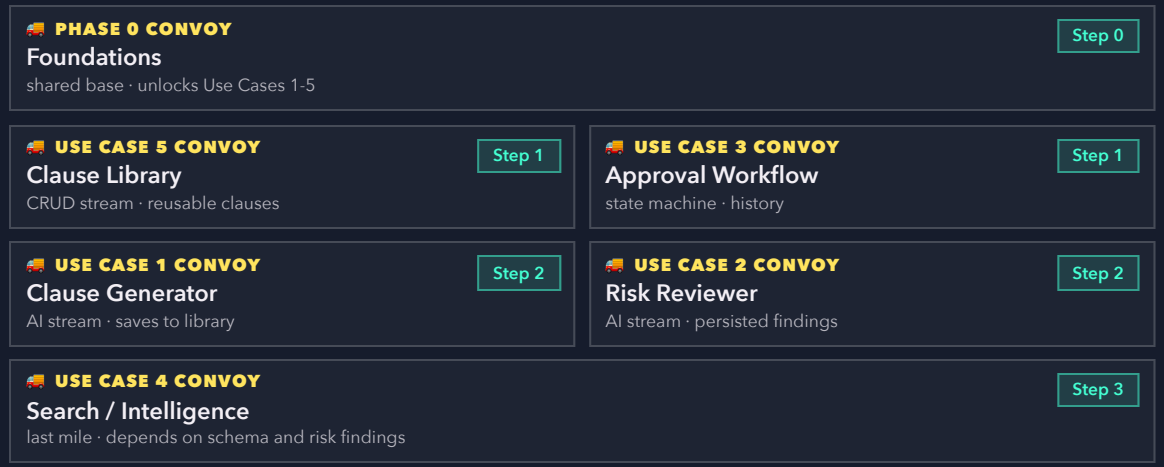

Beads turn a high-level request into executable work with order, ownership, and status.

- Dependencies expose the critical path.
- Ready work can be executed immediately.
- Blocked work is visible instead of implicit.
- Hooks keep workers connected to active assignments.

TAKEAWAY
Beads expose what can start now, what is blocked, and why.

LIVE SIGNAL Bead creation, ready/blocked status, dependency graph, and current hook.

Convoys: delivery streams

WHY IT MATTERS

Convoys make each use case visible as a delivery stream.

- Same step number means parallel work.
- Progress becomes visible across workers.
- Shared reference across roles.

TAKEAWAY
Convoys turn the bead graph into observable delivery streams.

LIVE SIGNAL Convoy creation, convoy status, and landing notification.

Polecats: parallel execution

POLECATS	BEADS
🐱 FURIOSA	Foundations Clause Library Risk Reviewer
🐱 NUX	Contract Approval Workflow
🐱 SLIT	Clause Generator Search / Intelligence MVP

ONE PRODUCT REQUEST
↓
SCOPED BEADS
↓
ISOLATED EXECUTION WORKERS (POLECATS)
↓
COORDINATED DELIVERY

WHY IT MATTERS

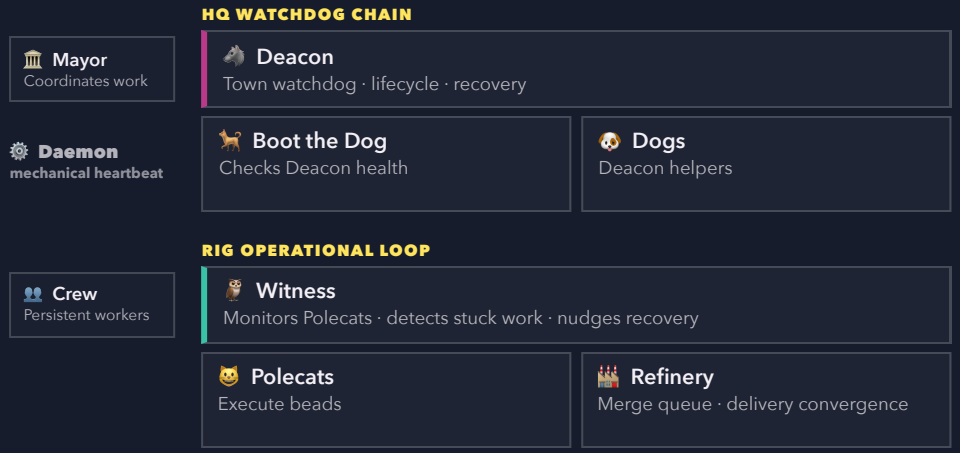

The Mayor assigns scoped beads to Polecats, each running in its own context and branch.

- Spawned on demand for discrete tasks.
- Assignments stay isolated from each other.
- Polecats disappear after delivery.
- Parallelism increases throughput, not chaos.

TAKEAWAY
Polecats make execution scalable by distributing work across isolated contexts.

LIVE SIGNAL Multiple Polecats, branches, commits, and delivery statuses running at the same time.

Supervision keeps execution operational

WHY IT MATTERS

Gas Town supervision is layered, not a single watcher.

- Daemon wakes Boot when health needs checking.
- Deacon keeps the town healthy.
- Witness keeps rig execution moving.
- Refinery keeps delivery converging.

TAKEAWAY
Supervision turns distributed execution into an operational system.

LIVE SIGNAL Deacon health, Witness status, Polecat recovery, Refinery queue, and delivery convergence.

Agreement Hub verification

LOCAL INSPECTION

We inspect the delivered repository by running Agreement Hub locally and comparing it with the starting version.

- The app is not deployed during the demo.
- We clone the complete repository produced by Gas Town.
- We run that repository locally, then compare it with the baseline app.

What will the delivered app reveal?

IMPLEMENTED USE CASES

Clause Generator	☑
Risk Reviewer	☑
Approval Workflow	☐
Search & Intelligence	☐
Clause Library	☐

VERIFICATION CHECKPOINT

The Gas Town delivery loop pauses here.

Now we clone the delivered repository, run Agreement Hub locally, and compare it with the starting application.

Open app ↗

Going further with formulas

FORMULA

A formula turns an orchestration pattern into a repeatable delivery playbook: steps, inputs, gates, parallel work, and artifacts.

EXAMPLE

mol-idea-to-plan

From vague idea to reviewed plan and work ready to become beads.

Open formula on GitHub

TAKEAWAY

Formulas make orchestration reusable: the workflow becomes part of the delivery system.

01 · YOU → CREW	Describe your idea in natural language; no structure needed.
02 · INTAKE	Agent structures it into a draft PRD.
03 · PRD-REVIEW	6 polecats review PRD in parallel: requirements, gaps, ambiguity, feasibility, scope and stakeholders.
04 · HUMAN-CLARIFY	Agent presents consolidated questions; the human answers before planning continues.
05 · GENERATE-PLAN	6 polecats design the implementation in parallel: API, data, UX, scale, security and integration.
06 · PRD-ALIGN 1-3	3 rounds × 2 Polecats align plan with PRD and apply fixes each round.
07 · PLAN-REVIEW 1-3	3 rounds × 2 Polecats review the plan itself: completeness, sequencing, risk, scope creep, testability and coherence.
08 · CREATE-BEADS	Agent converts the refined plan into beads with dependencies.
09 · VERIFY-BEADS	3 sequential passes compare plan to beads and fill gaps.

What Gas Town changed

	PROBLEM **Single-agent workflows break when coding becomes delivery.**	GAS TOWN RESPONSE **Turn delivery into a supervised, distributed operating model.**
01	**Context saturation** Important constraints disappear as the session grows.	Structure work into beads, artifacts, and explicit handoffs.
02	**Sequential execution** Throughput is bounded by one worker loop.	Use Polecats to execute independent work in parallel.
03	**No coordination layer** Dependencies and ownership stay implicit.	Mayor, Crew and Convoys make ownership and progress visible.
04	**Merge pressure** Parallel changes become hard to integrate safely.	Refinery manages convergence instead of leaving integration to chance.
05	**No operational supervision** Stuck work is difficult to observe and recover.	Witness, Deacon and recovery loops keep execution observable.

Thank you

Questions & discussion

EXAMPLE QUESTIONS

What does it cost to deliver a feature with Gas Town?

How much control do we have over the models?

When should we use the Crew instead of only the Mayor?
